

## 2012 State Silage Corn Performance Test on the Texas High Plains

Wenwei Xu<sup>1\*</sup>, Thomas Marek<sup>2</sup>, J. Wade Howard<sup>3</sup>, Jill Breeden<sup>3</sup>, Casey Hardin<sup>4</sup>, and Dennis Pietsch<sup>5</sup>

### Introduction

The significant dairy and beef industries in the Texas High Plains require large amount of grain and silage corn. Selection of a hybrid with high tonnage potential and acceptable quality is a key decision that a producer continually faces. We initiated the state silage corn performance test at the Texas A&M AgriLife North Plains Research Field at Etter in 2007, and at the Texas A&M AgriLife Research Station at Halfway in 2008 (Xu et al, 2007; 2009). Since then, we have conducted the tests at both locations annually. The interest among producers and seed industry regarding this program's data remains strong. Almost all seed companies that offer corn hybrids in this region have participated in the tests, and the number of hybrids entered annually continues to grow. Commercial seed companies have an opportunity to enter hybrids at either or both test sites, which is fee-based. To our knowledge, this is the only public comparative field testing program available in the Texas High Plains. The goal is to provide producers with timely and unbiased performance information regarding yield, quality, and agronomic traits.

### Entries of 2012 State Silage Corn Performance Test at Etter and Halfway:

The 2012 State Silage Corn Performance Test included 35 hybrids at Etter and 33 at Halfway submitted by seven companies (Tables 1 and 3). Thirty-one hybrids were common in both locations. In addition, 15 experimental hybrids from the Texas A&M AgriLife Corn Breeding Program in Lubbock were included at each location. These are the testcrosses of the brown midrib (BMR) inbred lines (carrying *bm1* gene) with a licensed proprietary non-BMR stiff-stalk tester. Four hybrids from Blue River Hybrids had no transgenic traits. The hybrids without transgenic traits are suitable for organic corn production. F2F626, F2F714, and the Texas A&M EX2012A have the BMR trait. Entry 50 at Etter is a brown midrib (*bm3*) hybrid where both parent lines were developed by the Texas A&M AgriLife Corn Breeding Program in Lubbock. Relative maturity is reported as per the seed companies and mostly ranges from 109-118 days.

### Experimental Designs:

The test was conducted under a center pivot field at the Texas A&M AgriLife North Plains Research Field at Etter and at the Texas A&M AgriLife Research Station at Halfway. The tests used a randomized complete block design with three replications. Each plot consisted of four rows, 17.5 feet long with 2.5-foot alleys. Row-spacing was 30-inches at Etter and 40 inches at Halfway. The two center rows of each plot were harvested for yield.

**Texas A&M AgriLife Research and Extension-Lubbock Center Technical Report No. 10-4.**

**Agronomic Practices at Etter:**

The test was planted on May 7 and harvested on September 7, 2012. The previous crop was wheat, followed by summer fallow. Pre-plant fertilizers were applied at the rate of 149.1 (N) lbs/a and 133 (P) lbs/a with a strip till rig on April 20. An additional 140 lbs. of nitrogen was applied through the pivot on June 20 and 26, and July 5, 11, 14, 23, and 30. A herbicide mixture of Bicep Lite II Magnum at 1.25 qt/a, Balance Flex at 3 oz/a, Medal II at 0.8 pt/a, and Mad Dog Plus at 1.5 pt/a was applied on April 5 to control weeds before planting. After planting, Mad Dog Plus at 40 oz/a and Sharpen at 2 oz/a were applied on May 14. On June 18, Option at 1.5 oz/a and Status at 8 oz/a were applied to control Johnson grass and other grassy weeds. Lorsban 15G was applied at 6.5 lbs/a through the planter units to control corn rootworm. At the three-leaf stage, seedlings were hand-thinned to a uniform target population of 33,852 plants/a. Strip till management was implemented without the listing of seedbeds. The test site had an adequate soil moisture profile level at planting. Monthly rainfall during the growing season was as follows: May – 0.0, June – 2.12, July 0.24, and August 1.45. Total rainfall from planting to harvest (May to August) was 4.41". The field was irrigated regularly at the 100% ET level through a center-pivot irrigation system fitted with LESA nozzles at 60" spacing. A total of 25.66 inches of water was applied during the season. During the growing season, plants were only slightly injured from a hail storm that occurred on June 14<sup>th</sup>. The plots within this field appeared very uniform.

**Agronomic Practices at Halfway:**

The test was planted on April 25 and harvested on September 4, 2012. The previous crop was cotton. Granular urea and mono-ammonium phosphate were broadcast on March 13 at the rate of 150 lbs. N/a and 30 lbs. P/a. Fertilizers were immediately incorporated into the soil by using an offset disk. Seedbeds were listed on January 9. Herbicides Aatrex at 1 qt/a and Roundup at 32 oz/a were applied on April 26 and activated by watering the field with the pivot. At three-leaf stage, seedlings were hand-thinned to achieve a uniform target population of 30,618 plants/a. On June 11, the herbicide Warrant was applied at 3 pt/a, and the liquid fertilizers were side dressed at 100 lbs, N/a. A total of 3.1 inches of water was applied between April 6 and April 24 prior to planting. From planting to harvest, a total of 21.34 inches of water was applied at regular intervals. In-season rainfall totaled 8.14 inches. With the high temperature and wind, the amount of irrigation water did not meet the plant evapotranspiration demand at 100% level.

**Data collected:**

Data was recorded for stand, flowering dates, plant and ear height, and root and stalk lodging. Stand is reported as a percentage of the target plant population. There was no root or stalk lodging in any plots at harvest in either location. The two-center rows of each plot were harvested with a John Deere 5200 small-plot silage chopper equipped with a Hagie silage plot weighing system. The plots were harvested on September 4 at Halfway, and September 7 at Etter. A mechanical problem with the silage chopper delayed harvesting 5-10 days later than the target date (average milk line at 50%), especially at Halfway where irrigation was withheld in preparation for harvesting. Plants were cut 5 inches above the ground. Approximately 2 lbs of a chopped sub-sample were collected from each plot, weighed for the fresh weight, dried at 50°C, weighed for dry weight, and then analyzed for silage quality using NIR methods by the Dairy One Forage Lab (Ithaca, NY). The moisture content was calculated by using fresh and dry weight of the sub-samples. Yields were measured on a plot basis, converted to short tons per acre, and adjusted to a 65% moisture level.

### **Test Results at Etter Location:**

The mean yield of all 50 hybrids was 33.5 tons/a, ranging from 27.3 to 39.7 tons/a (Table 1). Three hybrids yielded significantly more than the average entry: BH Genetics XP8977RR/HX (39.7 tons/a), Golden Acre GAX6156RR (39.0 tons/a), and Mycogen TMF2L825 (37.3 tons/a). The average silage yield of the State Silage Corn State at Etter increased about 10% from 2007 to 2012. Stands averaged 95.5% overall and most hybrids had excellent stands. There was no noticeable root and stalk lodging at harvest. Days from planting to pollen shed averaged 66.3. Whole plant moisture at harvest averaged 59.6% and ranged from 53.0% to 71.6%. Due to mechanical problems with our silage chopper, harvesting at this location was delayed about 5 days from the targeted harvesting date. In preparation for harvesting, irrigation was suspended before the target harvest date. Consequently, the plants dried down quickly under the high daily temperatures. Plants of the top five yielding hybrids were all above 10 feet tall (Table 1). The C.V. values of 6.7% for forage yield and 4.4% for forage moisture indicate that this was a very uniform test; the field was well managed; plant population was uniform; and that fertilizer and water were adequate. Silage quality was analyzed with NIR and all analyzed quality traits were highly different among the entries (Table 2). Users should consider different quality traits, but TDN and IVTN24 are commonly used to represent forage digestibility. In this test, TDN values ranged from 65.0% to 79% with an average of 71.8%, IVTD24 values ranged from 69.0% to 83.5%. A high value of TDN and IVTD24 indicates a higher digestibility. Digestibility of corn silage is also highly correlated to the amount of grain produced and also the chemical composition of the stalk.

### **Test Results at Halfway Location:**

The average forage yields of the 50 hybrids tested at the Halfway was 27.8 tons/a, ranging from 20.5 tons/a to 36.2 tons/a (Table 3). Only one hybrid (Entry 48, 36.2 tons/a) had a yield significantly higher than the test mean. The yield at Halfway was much lower than the Etter location, probably due to the following three factors: less irrigation water applied due to limited well capacity, a wider row spacing (40 inches vs. 30 inches) and higher daily temperatures. All hybrids had good plant stands, equal to or close to the target population of 31,954 plants per acre. The maturity of the hybrids was different. The days from planting to pollen shed ranged from 64 to 74 with an average of 73. The whole plant moisture at harvest averaged 46.6%, which was much lower than the target level of 65%. As indicated in the previous section, mechanical problems with the silage chopper delayed the harvesting of this test about one week. The genetic difference in silage quality traits at this location was insignificant except for CP and lignin (Table 4).

### **Summary**

Hybrid selection is an important decision for silage corn producers. A good silage hybrid should have a strong adaptation to local environment, appropriate maturity, high tonnage and digestibility, and stable production performance across varying environments. New silage hybrids have been introduced in the Texas High Plains since we started this test at Etter in 2007. The average silage yield of all entries at Etter has increased about 10% over the last six years. The averaged tonnage per acre was 29.98 in 2007, 29.32 in 2008, 32.58 in 2009, 31.3 in 2010, 32.96 in 2011, and 33.5 in 2012. Considering the similar crop management practices at this location, the yield increase is possibly due to improved genetics entered into this test. All silage corn in the High Plains is virtually produced with irrigation water derived from the Ogallala

Aquifer. More tonnage per acre is a good indicator of genetic improvement of crop water use efficiency and better genetics adapted to this environment.

These results are available at the State Crop Performance Test Program (<http://varietytesting.tamu.edu>) and the Texas A&M AgriLife Research Lubbock Center websites (<http://lubbock.tamu.edu>). These results will help producers, Extension specialists and consultants select commercial hybrids best suited in the Texas High Plains.

1. IVTD24: *In vitro* true digestibility (IVTD) after 24 hours of incubation in rumen fluid. It measures digestibility and can be used to estimate energy. A higher value of IVTD 24 hr presents a better forage quality.

2. Forage nutritional values based on NIR analysis.

ADF: Acid detergent fiber, a measure of cellulose and lignin. ADF is negatively correlated with overall digestibility.

CP: Crude protein, the total protein in the sample including true protein and non-protein nitrogen.

Lignin: undigestible plant component and has a negative impact on cellulose digestibility.

NDF: Neutral detergent fiber, a measure of hemicellulose, cellulose and lignin representing the fibrous bulk of the forage. NDF is negatively correlated with intake

NFC: Percentage of non-fibrous carbohydrates; estimates the amount of rapidly digestible carbohydrates in a forage.

NDFD24: Percentage of NDF that is digestible by *in vitro* incubation.

MILK 1: Estimated lbs. of milk produced per ton of dry matter.

MILK 2: Estimated lbs. of milk produced per ton of processed dry matter.

Starch: primarily in the grain, later maturing hybrids have lower starch since all hybrids were harvested at the same time.

TDN: Total digestible nutrients. It represents the sum of the digestible protein, digestible nitrogen-free extract, digestible crude fiber and 2.25X the digestible fat.

Milk lbs./ton of DM: an estimated potential milk yield per ton of forage dry matter based on digestibility and energy content of the forage.

1. IVTD24: *In vitro* true digestibility (IVTD) after 24 hours of incubation in rumen fluid. It measures digestibility and can be used to estimate energy. A higher value of IVTD 24 hr presents a better forage quality.

2. Forage nutritional values based on NIR analysis.

ADF: Acid detergent fiber, a measure of cellulose and lignin. ADF is negatively correlated with overall digestibility.

CP: Crude protein, the total protein in the sample including true protein and non-protein nitrogen.

Lignin: undigestible plant component and has a negative impact on cellulose digestibility.

NDF: Neutral detergent fiber, a measure of hemicellulose, cellulose and lignin representing the fibrous bulk of the forage. NDF is negatively correlated with intake

NFC: Percentage of non-fibrous carbohydrates; estimates the amount of rapidly digestible carbohydrates in a forage.

NDFD24: Percentage of NDF that is digestible by *in vitro* incubation.

MILK 1: Estimated lbs. of milk produced per ton of dry matter.

MILK 2: Estimated lbs. of milk produced per ton of processed dry matter.

Starch: primarily in the grain, later maturing hybrids have lower starch since all hybrids were harvested at the same time.

TDN: Total digestible nutrients. It represents the sum of the digestible protein, digestible nitrogen-free extract, digestible crude fiber and 2.25X the digestible fat.

Milk lbs./ton of DM: an estimated potential milk yield per ton of forage dry matter based on digestibility and energy content of the forage.
