when broadcast), and spinosad (works in several weeks). They may need to be reapplied more often than slower acting and longer lasting products such as abamectin, methoprene or pyriproxyfen, which work in 1 to 2 months when applied in spring and 6 months when applied in fall. Products that combine fast- and slow-acting ingredients, such as hydramethylnon plus methoprene (Extinquish® Plus, Amdro® Firestrike), may control ants better because they act quickly and last longer.

To broadcast bait products correctly, you will need a standard lawn spreader or a hand-held spreader. To cover larger areas, use a vehicle-mounted spreader such as the Herd® GT-77. Most baits are applied at very low rates such as 1 to 2 pounds of product per acre. Calculate the area to be treated and use the smallest spreader setting that allows bait to flow. Apply the bait in swathes, crisscrossing the fertilizer spreader and must be watered in after treatment. Every treatment approach for each area. Make a schedule for treatments are most effective when ants are nesting close to the mound surface (as they do when the temperature is mild). Colonies should not be disturbed during treatment. If you use a watering can to apply insecticide, do not use it more than 20 per acre) or where you want to preserve native ants.

**Individual Mound Treatments**

Although treating ant mounds individually is more labor intensive and may use more insecticide than other methods, it is a suitable approach for small areas with few fire ant mounds (fewer than 20 per acre) or where you want to preserve native ants. Faster-acting bait products (hydramethylnon, indexoxacarb, spinosad) can be used to treat individual ant mounds and are ideal for treating inaccessible colonies like those nesting under sidewalks, in plant beds and at the bases of tree trunks. Some mound treatment products are available as liquid drenches, injectable aerosols, dusts, or granules that are watered in to the mound. Ants are killed only if the insecticide contacts them, so proper application is essential. These treatments are most effective when ants are nesting close to the mound surface (as they do when the temperature is mild). Colonies should not be disturbed during treatment. If you use a watering can to apply insecticide, do not use it more than 20 per acre) or where you want to preserve native ants.

### Make a Management Plan

Chemical control lasts only as long as the effects of the insecticide used, until the specified amount is applied. The agitators in some spreaders may cause bait to cake up swaths if needed, until the specified amount is applied. Faster-acting contact insecticides, such as the pyrethroids (listed above), eliminate ants on the surface for months but may not eliminate colonies nesting deeper in the soil.

**Granular Fipronil Products**

Granular fipronil products are slower acting but longer lasting; only one treatment is permitted per year. Faster-acting contact insecticides, such as the pyrethroids (listed above), eliminate ants on the surface for months but may not eliminate colonies nesting deeper in the soil.

### Other Approaches

#### Granular Products

- Granular fipronil products are slower acting but longer lasting; only one treatment is permitted per year. Faster-acting contact insecticides, such as the pyrethroids (listed above), eliminate ants on the surface for months but may not eliminate colonies nesting deeper in the soil.

Fire ants cost Americans $6 billion a year, including the cost of insecticides. The Two-Step Method and other approaches described here can lower that cost while reducing environmental damage and improving fire ant control. Knowing your options will allow you to make better choices to protect your family, pets and property. Most people (about 80 percent according to one survey) try to control fire ants by treating the mounds. Mound treatments are expensive—up to $2 or so per mound—and require lots of time and labor if you have much land to treat. With mound treatments, it may be easy to use too much insecticide, which can lead to environmental contamination if rain washes insecticide into lakes and streams. Mound treatments also can be ineffective. For one thing, some nests may go undetected. But even an area where every mound has been treated can soon be reinfested by fire ant colonies migrating from untreated areas or floating there on flood water. Also, deep-dwelling fire ants are especially hard to control, especially in large areas. Your objective should be to find the method or methods that are most cost-effective and environmentally sound. In areas where these ants do not present problems, doing nothing is certainly one option.

### Control Products

#### Biological control

Governing and university researchers have imported and tested natural enemies of fire ants, such as the parasitic phorid flies from South America. These natural enemies have been successful in areas where they have been released. However, the biological control agents available on the retail market, such as parasitic nematodes, do not sustain themselves or spread on their own once they are released.

#### Home remedies

Many home remedies have been devised to control fire ants. Drenching a mound with 2 to 3 gallons of almost boiling water eliminates ant colonies about 60 percent of the time, but it will also kill any plants the water contacts. This method is labor intensive and the hot water must be handled carefully. Some home remedies are considered beneficial insects. Collectively, they may do more harm than good. Fire ants will build their mounds almost anywhere—in the open or next to a building, tree, sidewalk or electrical box. A fire ant mound does not have a central opening. When the mound is disturbed, fire ants emerge quickly and begin biting and stinging. They will even run up vertical surfaces.

Worker fire ants are dark reddish-brown with shiny black abdomens, and are about 1⁄8 to about 1⁄4 inch long.

### Controlling Fire Ants

The current USDA quarantine for imported fire ants covers 320 million acres in all or parts of 14 U.S. states and territories (Alabama, Arkansas, California, Florida, Georgia, Louisiana, Mississippi, New Mexico, North Carolina, Oklahoma, South Carolina, Tennessee, Texas and Puerto Rico). The quarantine means that shipments of hay, nursery stock, sod and other articles from quarantined counties must comply with state regulations.

Most active ingredients can’t be eliminated entirely because it’s not possible to treat all areas that are infested. Thus, the goal of current integrated pest management (IPM) programs is to suppress fire ants as much as possible with biological control methods and other adequate techniques. The goal is economically and environmentally justifiable to do so.

There may not be one “best” method for fire ant control, especially in large areas. Your objective should be to find the method or methods that are most cost-effective and environmentally sound. The Two-Step Method and other approaches described here can lower that cost while reducing environmental damage and improving fire ant control. Knowing your options will allow you to make better choices to protect your family, pets and property.

#### Organic products

A few treatments are certified as organic. These include insecticides such as d-limonene, an extract from citrus fruit, or spinosad, a chemical complex produced by a soil microbe.

### Insect control

Control of fire ants is normally regulated by the Environmental Protection Agency. Approved products must be used according to directions on the labels. Be sure a product is registered for the kind of application site where you intend to use it, particularly if you will be treating a vegetable garden or other food production site. There are special products for use in electrical utility boxes and indoors, but they may not be available at retail stores. Some products are for use only by professional pest control operators. This publication refers to the generic names of the active ingredients in insecticides, which you should look for on the product labels. Most active ingredients are marketed under more than one brand or trade name. Some sample trade names and generic names are given as well.

### Step 1: Broadcast

#### Broadcast treatments

**Products**

- Amdro Pro®, Esteem®, Extinguish®, and Extinguish Plus®

- Spectracide® Fire Ant Bait

-距离® Ant Control

- A relatively new type of bait combines two different active ingredients, hydramethylnon and methoprene (AMDRo FireStrike® or Extinguish Plus®). To be effective, baits must be fresh and applied when ants are actively foraging. To determine if the time is right for treatment, place a small amount of bait in the area to be treated and see if foraging ants remove it within an hour. Because ants collect bait and return it to the colony, very little insecticide is needed in this formulation. Baits are ruined by weather, so do not place baits after application or apply them when rain is expected.

### Control Approaches

#### The Two-Step Method

Step 1. Broadcasting an insecticide bait once or twice a year, which reduces fire ant colonies by 80 to 90 percent.

Step 2. Treating nuisance mounds or colonies that move into the bait-treated areas. Step 2 may not be needed.

This is likely to be the most cost-effective and environmentally sound approach to treating medium-size to large landscape areas. Certified organic products can be used for broadcast bait and mound treatments. For livestock pastures, select products registered for use on such sites, such as Amdro Pro®, Esteem®, Extinguish®, or Extinguish Plus®.

The bait you apply determines how quickly ants will be controlled and how long the effect will last. Faster-acting bait products include indoxacarb (works in 3 to 10 days), hydramethylnon (works in 7 to 14 days for mound treatments and in 2 to 3 weeks) and fipronil. Some affect the digestive system (boric acid) or metabolism (hydramethylnon or Amdro®). Other bait ingredients interfere with reproduction or growth; these include fenoxycarb (Amdro® Tablets), methoprene (Extinguish®) and pyriproxyfen (Distance®). A relatively new type of bait combines two different active ingredients, hydramethylnon and methoprene (AMDRo FireStrike® or Extinguish Plus®). To be effective, baits must be fresh and applied when ants are actively foraging.
